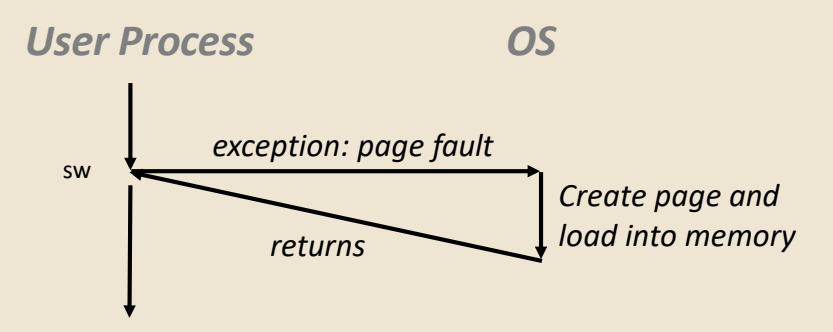
Computer System Architecture

Virtual Memory

Fault Example: Page Fault

- User writes to memory location
- That portion (page) of user's memory is currently on disk

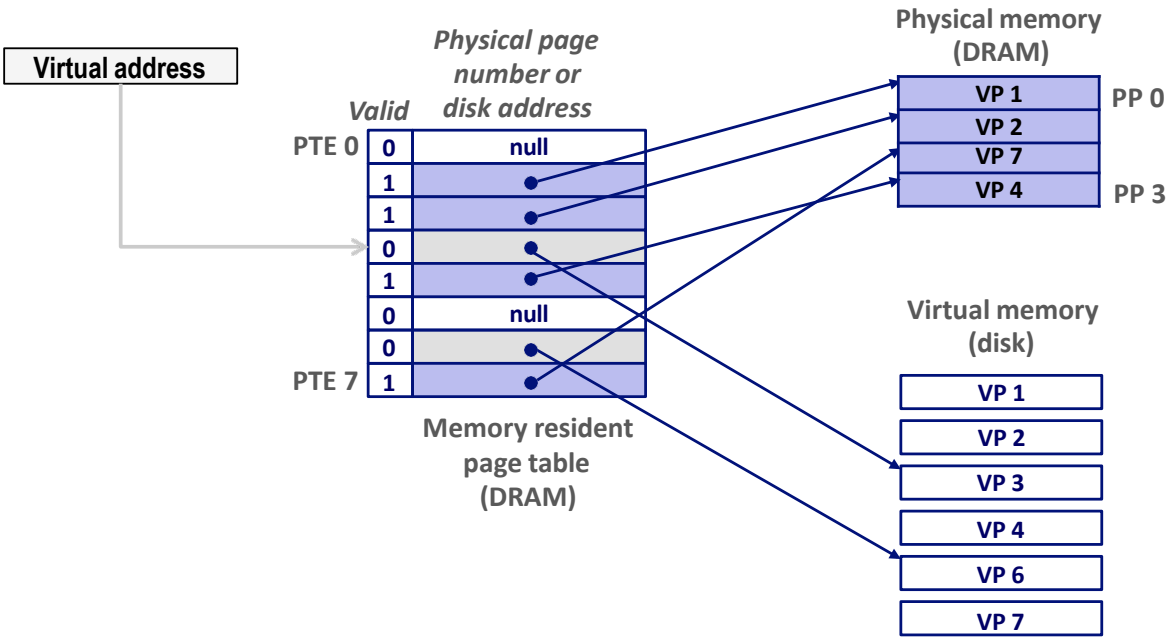
```
int a[1000];
main ()
{
    a[500] = 13;
}
```



- Page handler must load page into physical memory
- Returns to faulting instruction
- Successful on second try

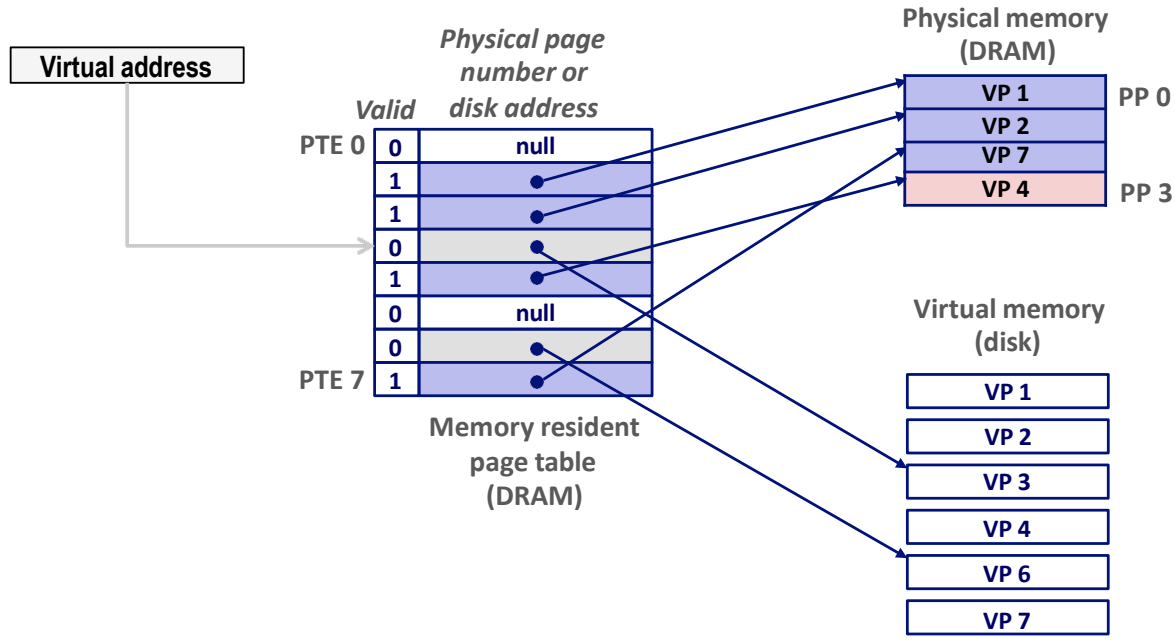
Handling Page Fault

- Page miss causes page fault (an exception)



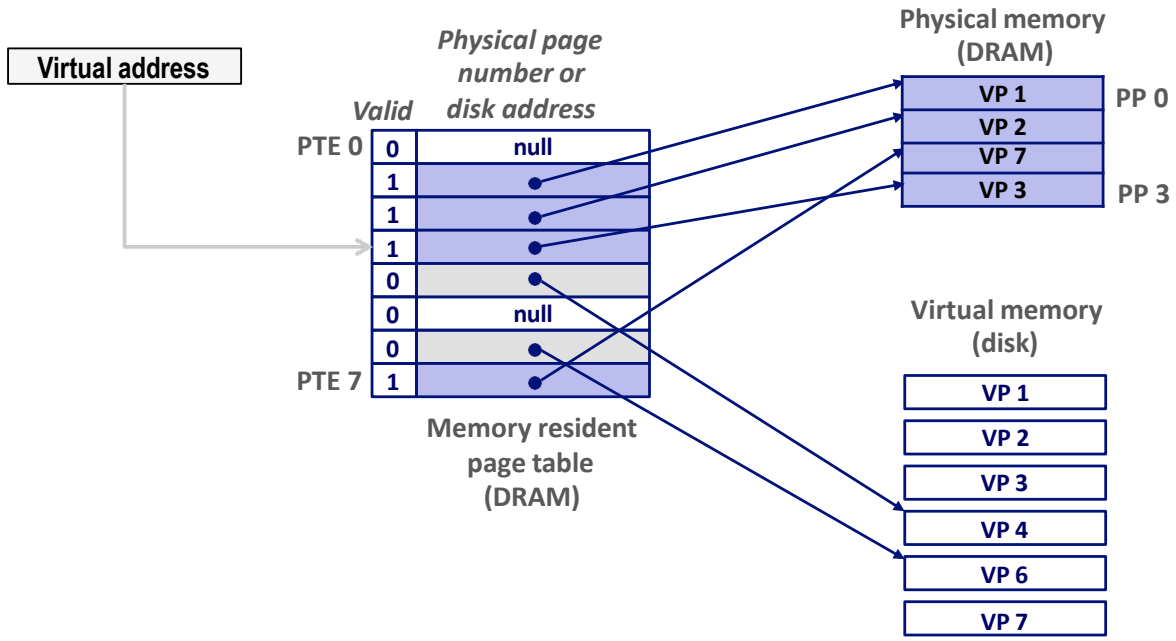
Handling Page Fault

- Page miss causes page fault (an exception)
- Page fault handler selects a victim to be evicted (here VP 4)



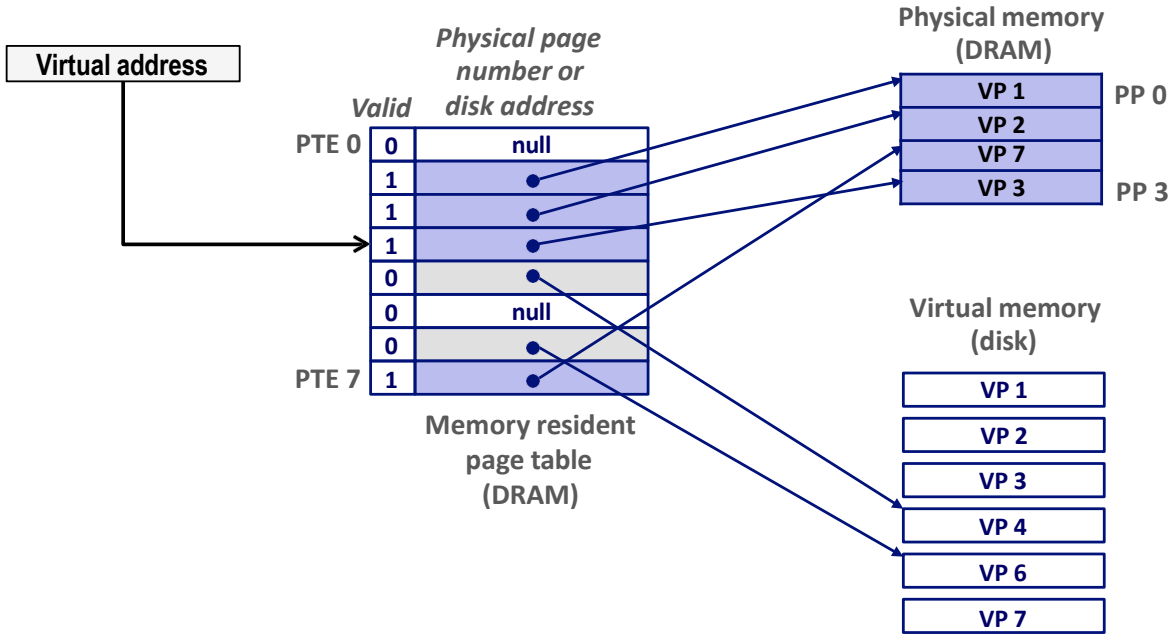
Handling Page Fault

- Page miss causes page fault (an exception)
- Page fault handler selects a victim to be evicted (here VP 4)



Handling Page Fault

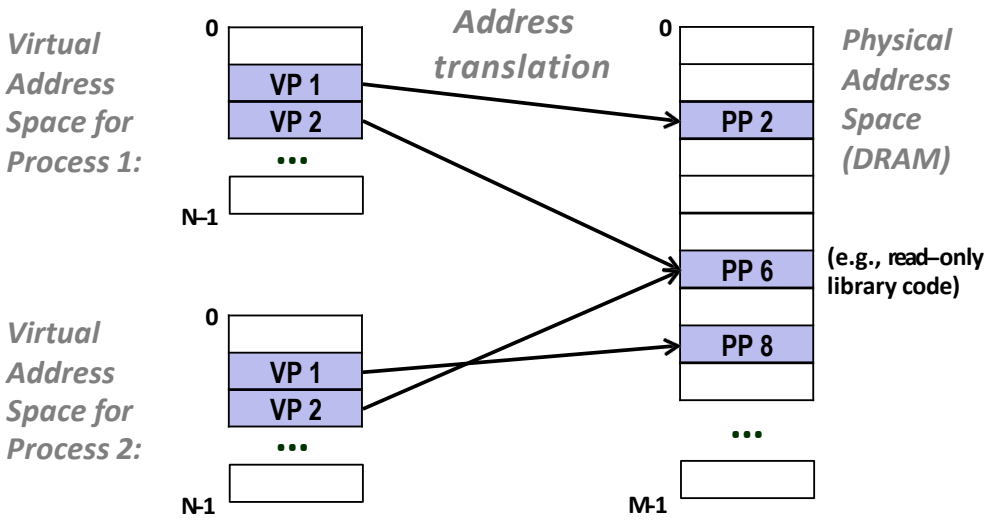
- Page miss causes page fault (an exception)
- Page fault handler selects a victim to be evicted (here VP 4)
- Offending instruction is restarted: page hit!



VM as a Tool for Memory Management

Key idea: each process has its own virtual address space

- It can view memory as a simple linear array
- Mapping function scakers addresses through physical memory
  - Well chosen mappings simplify memory allocation and management



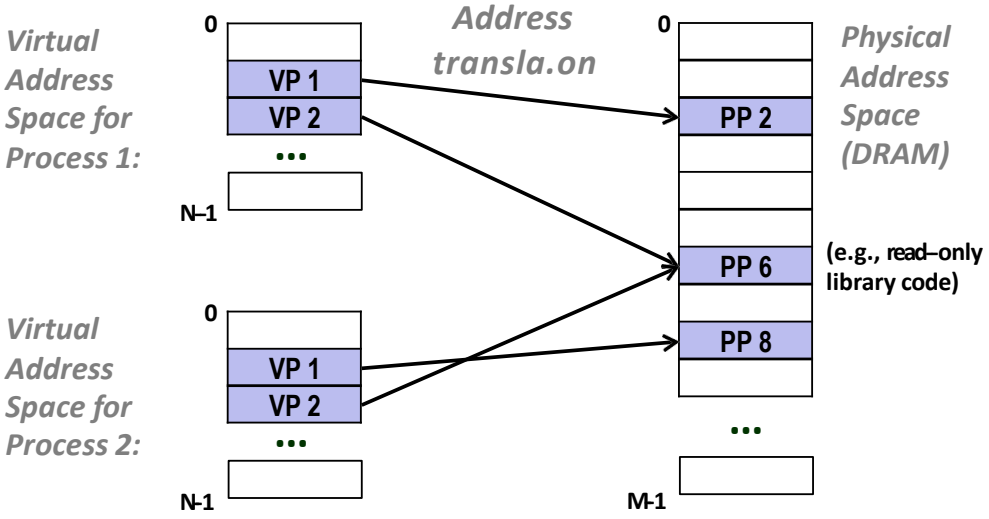
VM as a Tool for Memory Management

Memory allocation

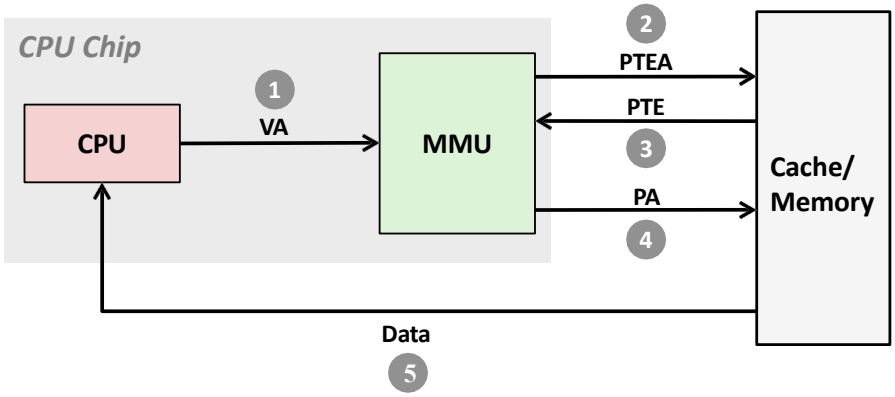
- Each virtual page can be mapped to any physical page
- A virtual page can be stored in different physical pages at different times

Sharing code and data among processes

- Map virtual pages to the same physical page (here: PP 6)



Address Translation: Page Hit



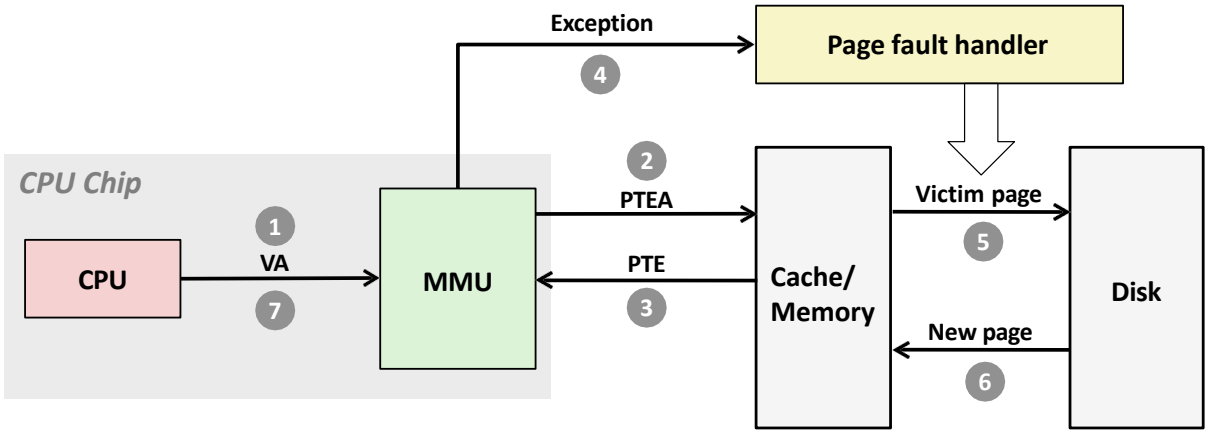
1) Processor sends virtual address to MMU

2–3) MMU fetches PTE from page table in memory

4) MMU sends physical address to cache/memory

5) Cache/memory sends data word to processor

Address Translation: Page Fault



1) Processor sends virtual address to MMU

2–3) MMU fetches PTE from page table in memory

4) Valid bit is zero, so MMU triggers page fault exception

5) Handler identifies victim (and, if dirty, pages it out to disk)

6) Handler pages in new page and updates PTE in memory

7) Handler returns to original process, restarting faulting instruction

Hmm… Translation sounds slow!

- What can we do?

TLB Hit

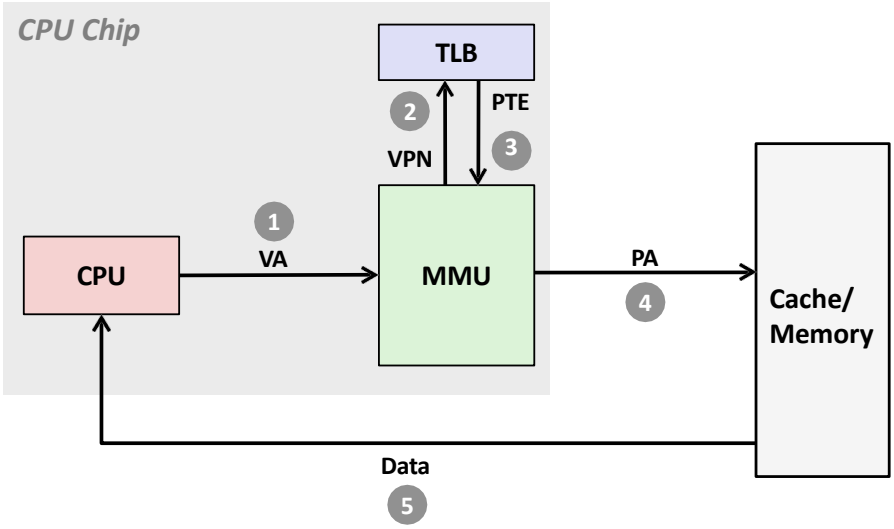
Page table entries (PTEs) are cached in L1 like any other memory word

- PTEs may be evicted by other data references
- PTE hit still requires a 1–cycle delay

Solution: *Translation Lookaside Buffer* (TLB)

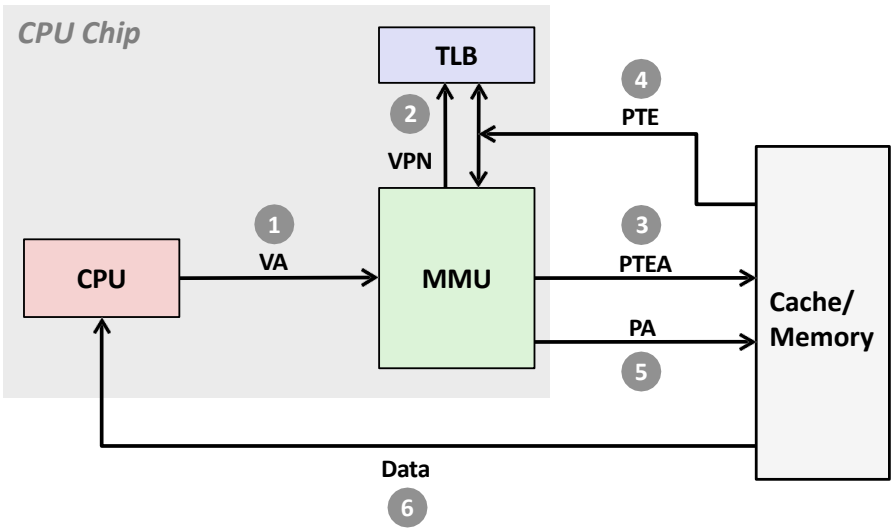
- Small hardware cache in MMU
- Maps virtual page numbers to physical page numbers
- Contains complete page table entries for small number of pages

Hmm… Translation sounds slow!



A TLB hit eliminates a memory access

TLB Miss



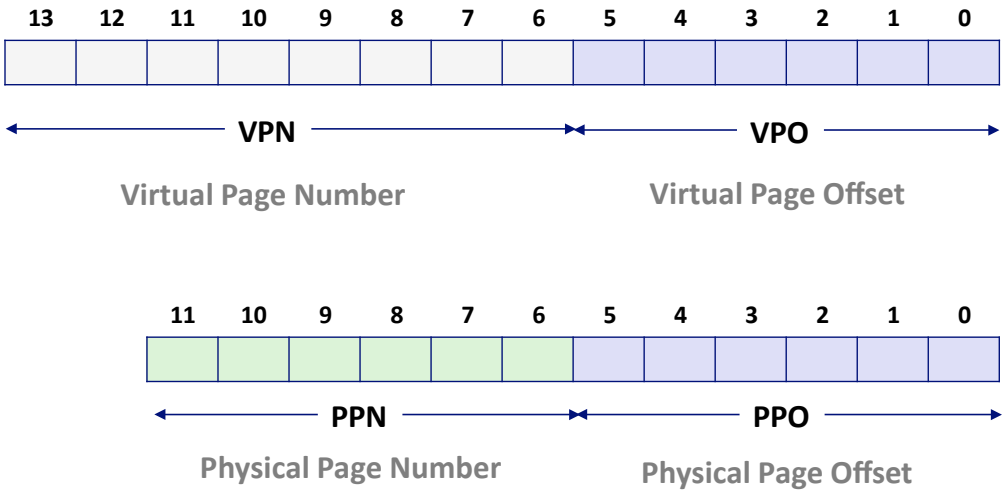
A TLB miss incurs an add'l memory access (the PTE)

Fortunately, TLB misses are rare

Simple Memory System Example

Addressing

- 14--bit virtual addresses
- 12--bit physical address
- Page size = 64 bytes



Simple Memory System Page Table

Only show first 16 entries (out of 256)
